

Simple Interest Calculator

A small Bash command-line tool that calculates simple interest based on user-provided input.

What it does

The script asks the user for three values and calculates the simple interest using the standard formula:

```
Simple Interest = (Principal × Rate × Time)  
/ 100
```

Input fields

- **Principal** — the initial amount of money (the loan or investment amount)
- **Rate of Interest** — the annual interest rate, as a percentage
- **Time Period** — the duration, in years

How to run it

```
chmod +x simple-interest.sh
./simple-interest.sh
```

The script will prompt you to enter the principal, rate of interest, and time period, then print the calculated simple interest.

Example

```
Enter the principal amount: 1000
Enter the rate of interest: 5
Enter the time period (in years): 2
The simple interest is: 100
```
